- Bayes Classification
- Maximum a-Posteriori Hypotheses

Bayes Classification

Theorem 12 (Bayes)

Let $(\Omega, \mathcal{P}(\Omega), P)$ be a probability space, and let A_1, \dots, A_k be mutually exclusive events with $\Omega = A_1 \cup \dots \cup A_k$, $P(A_i) > 0$, $i = 1, \dots, k$. Then for a $B \in \mathcal{P}(\Omega)$ with $P(B) > 0$ holds:

$$P(A_i \mid B) = \frac{P(A_i) \cdot P(B \mid A_i)}{\sum_{i=1}^k P(A_i) \cdot P(B \mid A_i)}$$

$P(A_i)$ is called *prior probability* of A_i .

$P(A_i \mid B)$ is called *posterior probability* of A_i .

Bayes Classification

Theorem 12 (Bayes)

Let $(\Omega, \mathcal{P}(\Omega), P)$ be a probability space, and let A_1, \dots, A_k be mutually exclusive events with $\Omega = A_1 \cup \dots \cup A_k$, $P(A_i) > 0$, $i = 1, \dots, k$. Then for a $B \in \mathcal{P}(\Omega)$ with $P(B) > 0$ holds:

$$P(A_i | B) = \frac{P(A_i) \cdot P(B | A_i)}{\sum_{i=1}^k P(A_i) \cdot P(B | A_i)}$$

$P(A_i)$ is called *prior probability* of A_i .

$P(A_i | B)$ is called *posterior probability* of A_i .

Proof

From the [conditional probabilities](#) for $P(B | A_i)$ and $P(A_i | B)$ follows:

$$P(A_i | B) = \frac{P(B \cap A_i)}{P(B)} = \frac{P(A_i) \cdot P(B | A_i)}{P(B)}$$

Applying the theorem of the [total probability](#) for $P(B)$ in the denominator will yield the claim of the theorem.

Bayes Classification

Combined Events

Let $P(A \mid B_1, \dots, B_p)$ denote the probability of the occurrence of event A given that the events B_1, \dots, B_p are known to have occurred.

Applied to a classification problem:

- A corresponds to an event of kind “class=c”, and the $B_j, j = 1, \dots, p$, correspond to p events of kind “attribute=value”.
- observable connection (standard situation): $B_1, \dots, B_p \mid A$
- reversed connection (diagnosis situation): $A \mid B_1, \dots, B_p$

Bayes Classification

Combined Events

Let $P(A \mid B_1, \dots, B_p)$ denote the probability of the occurrence of event A given that the events B_1, \dots, B_p are known to have occurred.

Applied to a classification problem:

- A corresponds to an event of kind “class=c”, and the B_j , $j = 1, \dots, p$, correspond to p events of kind “attribute=value”.
- observable connection (standard situation): $B_1, \dots, B_p \mid A$
- reversed connection (diagnosis situation): $A \mid B_1, \dots, B_p$

If sufficient data for estimating $P(A)$ and $P(B_1, \dots, B_p \mid A)$ is provided, then $P(A \mid B_1, \dots, B_p)$ can be computed with the theorem of Bayes:

$$P(A \mid B_1, \dots, B_p) = \frac{P(A) \cdot P(B_1, \dots, B_p \mid A)}{P(B_1, \dots, B_p)} \quad (\star)$$

Remarks [\[Information gain for classification\]](#) :

- ❑ How probability theory is applied to classification problem solving:
 - Classes and attribute-value pairs are interpreted as events. The relation to an underlying sample space $\Omega = \{\omega_1, \dots, \omega_n\}$, from which the events are subsets, is not considered.
 - Observable or measurable, possibly causal connection: it is (or was in the past) regularly observed that in situation A (e.g. a disease) the symptoms B_1, \dots, B_p occur. One may denote this as forward connection.
 - Reversed connection, typically an analysis or diagnosis situation: the symptoms B_1, \dots, B_p occur, and one is interested in the likelihood that A is given or has been occurred.
 - Based on the prior probabilities of the classes (aka class priors), $P(\text{class}=\text{c})$, and the probabilities of the observable connections, $P(\text{attribute}=\text{value} \mid \text{class}=\text{c})$, the conditional class probabilities in an analysis situation, $P(\text{class}=\text{c} \mid \text{attribute}=\text{value})$, can be computed with the theorem of Bayes.
- ❑ The class-conditional event “attribute=value | class=c” does not necessarily model a cause-effect relation: the event “class=c” *may* cause—but does not need to cause—the event “attribute=value”.

Remarks (continued) :

- $P(A \mid B_1, \dots, B_p)$ is called conditional probability of A given the conditions B_1, \dots, B_p .
- Alternative, semantically equivalent notations of $P(A \mid B_1, \dots, B_p)$ are:
 1. $P(A \mid B_1, \dots, B_p)$
 2. $P(A \mid B_1 \wedge \dots \wedge B_p)$
 3. $P(A \mid B_1 \cap \dots \cap B_p)$

Bayes Classification

Naive Bayes

The compilation of a database from which reliable values for the $P(B_1, \dots, B_p \mid A)$ can be obtained is often infeasible. The way out:

- (a) Naive Bayes Assumption: “Given condition A , the B_1, \dots, B_p are statistically independent” (aka: the B_i are conditionally independent). Formally:

$$P(B_1, \dots, B_p \mid A) \stackrel{NB}{=} \prod_{j=1}^p P(B_j \mid A)$$

Bayes Classification

Naive Bayes

The compilation of a database from which reliable values for the $P(B_1, \dots, B_p \mid A)$ can be obtained is often infeasible. The way out:

- (a) Naive Bayes Assumption: “Given condition A , the B_1, \dots, B_p are statistically independent” (aka: the B_i are conditionally independent). Formally:

$$P(B_1, \dots, B_p \mid A) \stackrel{NB}{=} \prod_{j=1}^p P(B_j \mid A)$$

- (b) $P(B_1, \dots, B_p)$ is constant and hence needs not to be estimated if one is interested only in the most likely event under the Naive Bayes Assumption, $A_{NB} \in \{A_1, \dots, A_k\}$. A_{NB} can be computed with the [theorem of Bayes](#) (★):

$$\operatorname{argmax}_{A \in \{A_1, \dots, A_k\}} \frac{P(A) \cdot P(B_1, \dots, B_p \mid A)}{P(B_1, \dots, B_p)} \stackrel{NB}{=} \operatorname{argmax}_{A \in \{A_1, \dots, A_k\}} P(A) \cdot \prod_{j=1}^p P(B_j \mid A) = A_{NB}$$

Remarks:

- ❑ Why the probabilities $P(B_1, \dots, B_p \mid A)$ usually cannot be estimated in the wild: Suppose that we are given k classes, and that the domains of the p attributes of a feature vector contain minimum l values each, then for as many as $k \cdot p^l$ different feature vectors (= class-features-values combinations) the probability values are required. In order to provide reliable estimates, each class-features-values combination must occur in the database sufficiently frequently. By contrast, the estimation of the probabilities $P(B \mid A)$ can be derived from a significantly smaller database since only $k \cdot p \cdot l$ combined events are distinguished altogether.
- ❑ If the Naive Bayes Assumption applies, then the event A_{NB} will maximize also the posterior probability $P(A \mid B_1, \dots, B_p)$ as defined by the [theorem of Bayes](#).
- ❑ Given a set of examples D , then “learning” or “training” a classifier using Naive Bayes means to estimate the prior probabilities (class priors) $P(A)$, where $A \in \{c(\mathbf{x}) \mid (\mathbf{x}, c(\mathbf{x})) \in D\}$, as well as the probabilities of the observable connections $P(B \mid A)$, where $B \in \{B_{j=x_j} \mid x_j \in \mathbf{x}, (\mathbf{x}, c(\mathbf{x})) \in D\}$ and $c(\mathbf{x}) = A$. The obtained probabilities are used in the argmax-term for A_{NB} , which hence encodes the learned hypothesis and functions as a classifier for new feature vectors.
- ❑ The hypothesis space H is comprised of all combinations that can be formed from all values that can be chosen for $P(A)$ and $P(B \mid A)$. When constructing a Naive Bayes classifier, the hypothesis space H is not explored, but the sought hypothesis is directly computed from an descriptive data analysis of D .
Keyword: *discriminative* classifier versus *generative* classifier

Bayes Classification

Naive Bayes (continued)

In addition to the [Naive Bayes Assumption](#), let the following conditions apply:

- (c) the set of the k classes is complete: $\sum_{i=1}^k P(A_i) = 1, A_i \in \{c(\mathbf{x}) \mid c(\mathbf{x}) \in D\}$
- (d) the A_i are mutually exclusive: $P(A_i, A_\iota) = 0, 1 \leq i, \iota \leq k, i \neq \iota$

Bayes Classification

Naive Bayes (continued)

In addition to the [Naive Bayes Assumption](#), let the following conditions apply:

- (c) the set of the k classes is complete: $\sum_{i=1}^k P(A_i) = 1, A_i \in \{c(\mathbf{x}) \mid c(\mathbf{x}) \in D\}$
- (d) the A_i are mutually exclusive: $P(A_i, A_\iota) = 0, 1 \leq i, \iota \leq k, i \neq \iota$

Then holds:

$$P(B_1, \dots, B_p) \stackrel{c,d}{=} \sum_{i=1}^k P(A_i) \cdot P(B_1, \dots, B_p \mid A_i) \quad (\text{theorem of total probability})$$

$$\stackrel{NB}{=} \sum_{i=1}^k P(A_i) \cdot \prod_{j=1}^p P(B_j \mid A_i) \quad (\text{Naive Bayes Assumption})$$

Bayes Classification

Naive Bayes (continued)

In addition to the [Naive Bayes Assumption](#), let the following conditions apply:

- (c) the set of the k classes is complete: $\sum_{i=1}^k P(A_i) = 1, A_i \in \{c(\mathbf{x}) \mid c(\mathbf{x}) \in D\}$
- (d) the A_i are mutually exclusive: $P(A_i, A_\iota) = 0, 1 \leq i, \iota \leq k, i \neq \iota$

Then holds:

$$\begin{aligned} P(B_1, \dots, B_p) &\stackrel{c,d}{=} \sum_{i=1}^k P(A_i) \cdot P(B_1, \dots, B_p \mid A_i) \quad (\text{theorem of total probability}) \\ &\stackrel{NB}{=} \sum_{i=1}^k P(A_i) \cdot \prod_{j=1}^p P(B_j \mid A_i) \quad (\text{Naive Bayes Assumption}) \end{aligned}$$

With the [theorem of Bayes](#) (★) it follows for the conditional probabilities:

$$P(A_i \mid B_1, \dots, B_p) = \frac{P(A_i) \cdot P(B_1, \dots, B_p \mid A_i)}{P(B_1, \dots, B_p)} \stackrel{c,d,NB}{=} \frac{P(A_i) \cdot \prod_{j=1}^p P(B_j \mid A_i)}{\sum_{i=1}^k P(A_i) \cdot \prod_{j=1}^p P(B_j \mid A_i)}$$

Remarks:

- ❑ A *ranking* of the A_1, \dots, A_k can be computed via $\operatorname{argmax}_{A \in \{A_1, \dots, A_k\}} P(A) \cdot \prod_{j=1}^p P(B_j \mid A)$.
- ❑ If both (c) completeness and (d) mutual exclusiveness of the A_i can be presumed, the total of all posterior probabilities must add up to one: $\sum_{i=1}^k P(A_i \mid B_1, \dots, B_p) = 1$.
As a consequence, the rank order values of the A_i can be converted into the prior probabilities $P(A_i \mid B_1, \dots, B_p)$. The normalization is obtained by dividing a rank order value by the rank order values total, i.e., $\sum_{i=1}^k P(A_i) \cdot \prod_{j=1}^p P(B_j \mid A_i)$.

Bayes Classification

Naive Bayes: Classifier Construction Summary

Let X be a p -dimensional feature space, let C be the set of k classes of a target concept, and let D be a set of examples of the form $(\mathbf{x}, c(\mathbf{x}))$ over $X \times C$. Then the k classes correspond to the events A_1, \dots, A_k , and the p feature values of some $\mathbf{x} \in X$ correspond to the events $B_{1=x_1}, \dots, B_{p=x_p}$.

Bayes Classification

Naive Bayes: Classifier Construction Summary

Let X be a p -dimensional feature space, let C be the set of k classes of a target concept, and let D be a set of examples of the form $(\mathbf{x}, c(\mathbf{x}))$ over $X \times C$. Then the k classes correspond to the events A_1, \dots, A_k , and the p feature values of some $\mathbf{x} \in X$ correspond to the events $B_{1=x_1}, \dots, B_{p=x_p}$.

Construction and application of a Naive Bayes classifier:

1. Estimation of the $P(A)$, where $A = c(\mathbf{x})$, $(\mathbf{x}, c(\mathbf{x})) \in D$.
2. Estimation of the $P(B_{j=x_j} \mid A)$, where $x_j \in \mathbf{x}$, $(\mathbf{x}, c(\mathbf{x})) \in D$, $c(\mathbf{x}) = A$.
3. Classification of a feature vector \mathbf{x} as A_{NB} , iff

$$A_{NB} = \operatorname{argmax}_{A \in \{A_1, \dots, A_k\}} \hat{P}(A) \cdot \prod_{\substack{x_j \in \mathbf{x} \\ j=1, \dots, p}} \hat{P}(B_{j=x_j} \mid A)$$

4. Given the conditions (c) and (d), computing of the posterior probabilities for A_{NB} as normalization of $\hat{P}(A_{NB}) \cdot \prod_{\substack{x_j \in \mathbf{x} \\ j=1, \dots, p}} \hat{P}(B_{j=x_j} \mid A_{NB})$.

Remarks:

- ❑ There are at most $p \cdot l$ different events $B_{j=x_j}$, if l is an upper bound for the size of the p feature domains.
- ❑ The probabilities, denoted as $P(_)$, are unknown and estimated by the relative frequencies, denoted as $\hat{P}(_)$.
- ❑ The Naive Bayes approach is adequate for example sets D of medium size up to a very large size.
- ❑ Strictly speaking, the Naive Bayes approach presumes that the feature values in D are “statistically independent given the classes of the target concept”. However, experience in the field of text classification shows that convincing classification results are achieved even if the Naive Bayes Assumption does not hold.
- ❑ If, in addition to the rank order values, also posterior probabilities shall be computed, both the completeness (c) and the exclusiveness (d) of the target concept classes are required. The first requirement is also called “*Closed World Assumption*”, the second requirement is also called “*Single Fault Assumption*”.

Bayes Classification

Naive Bayes: Example

	Outlook	Temperature	Humidity	Wind	EnjoySport
1	sunny	hot	high	weak	no
2	sunny	hot	high	strong	no
3	overcast	hot	high	weak	yes
4	rain	mild	high	weak	yes
5	rain	cold	normal	weak	yes
6	rain	cold	normal	strong	no
7	overcast	cold	normal	strong	yes
8	sunny	mild	high	weak	no
9	sunny	cold	normal	weak	yes
10	rain	mild	normal	weak	yes
11	sunny	mild	normal	strong	yes
12	overcast	mild	high	strong	yes
13	overcast	hot	normal	weak	yes
14	rain	mild	high	strong	no

Let the target concept $c(\mathbf{x})$ of feature vector $\mathbf{x} = (\textit{sunny}, \textit{cool}, \textit{high}, \textit{strong})$ be unknown.

Bayes Classification

Naive Bayes: Example (continued)

Computation of A_{NB} for \mathbf{x} :

$$\begin{aligned}\underline{A_{NB}} &= \operatorname{argmax}_{A \in \{\text{yes}, \text{no}\}} \hat{P}(A) \cdot \prod_{\substack{x_j \in \mathbf{x} \\ j=1, \dots, 4}} \hat{P}(B_{j=x_j} \mid A) \\ &= \operatorname{argmax}_{A \in \{\text{yes}, \text{no}\}} \hat{P}(A) \cdot \hat{P}(\text{Outlook}=\text{sunny} \mid A) \cdot \hat{P}(\text{Temperature}=\text{cool} \mid A) \cdot \\ &\quad \hat{P}(\text{Humidity}=\text{high} \mid A) \cdot \hat{P}(\text{Wind}=\text{strong} \mid A)\end{aligned}$$

Bayes Classification

Naive Bayes: Example (continued)

Computation of A_{NB} for \mathbf{x} :

$$\begin{aligned}\underline{A_{NB}} &= \operatorname{argmax}_{A \in \{\text{yes}, \text{no}\}} \hat{P}(A) \cdot \prod_{\substack{x_j \in \mathbf{x} \\ j=1, \dots, 4}} \hat{P}(B_{j=x_j} \mid A) \\ &= \operatorname{argmax}_{A \in \{\text{yes}, \text{no}\}} \hat{P}(A) \cdot \hat{P}(\text{Outlook}=\text{sunny} \mid A) \cdot \hat{P}(\text{Temperature}=\text{cool} \mid A) \cdot \\ &\quad \hat{P}(\text{Humidity}=\text{high} \mid A) \cdot \hat{P}(\text{Wind}=\text{strong} \mid A)\end{aligned}$$

“ $B_{j=x_j}$ ” denotes the event for a particular attribute-value-combination in \mathbf{x} , namely, that event where attribute (dimension) j has value x_j .

The feature vector $\mathbf{x} = (\text{sunny}, \text{cool}, \text{high}, \text{strong})$ with the unknown target concept gives rise to the following four events:

$B_{1=x_1} : \text{Outlook}=\text{sunny}$

$B_{2=x_2} : \text{Temperature}=\text{cool}$

$B_{3=x_3} : \text{Humidity}=\text{high}$

$B_{4=x_4} : \text{Wind}=\text{strong}$

Bayes Classification

Naive Bayes: Example (continued)

For the classification of \mathbf{x} altogether $2 + 4 \cdot 2$ probabilities have to be estimated:

- $\hat{P}(\textit{EnjoySport}=\textit{yes}) = \frac{9}{14} = 0.64$
- $\hat{P}(\textit{EnjoySport}=\textit{no}) = \frac{5}{14} = 0.36$
- $\hat{P}(\textit{Wind}=\textit{strong} \mid \textit{EnjoySport}=\textit{yes}) = \frac{3}{9} = 0.33$
- ...

Bayes Classification

Naive Bayes: Example (continued)

For the classification of \mathbf{x} altogether $2 + 4 \cdot 2$ probabilities have to be estimated:

- $\hat{P}(\text{EnjoySport}=\text{yes}) = \frac{9}{14} = 0.64$
- $\hat{P}(\text{EnjoySport}=\text{no}) = \frac{5}{14} = 0.36$
- $\hat{P}(\text{Wind}=\text{strong} \mid \text{EnjoySport}=\text{yes}) = \frac{3}{9} = 0.33$
- ...

→ Ranking:

1. $\hat{P}(\text{EnjoySport}=\text{no}) \cdot \prod_{x_j \in \mathbf{x}} \hat{P}(B_{j=x_j} \mid \text{EnjoySport}=\text{no}) = 0.0206$
2. $\hat{P}(\text{EnjoySport}=\text{yes}) \cdot \prod_{x_j \in \mathbf{x}} \hat{P}(B_{j=x_j} \mid \text{EnjoySport}=\text{yes}) = 0.0053$

Bayes Classification

Naive Bayes: Example (continued)

For the classification of \mathbf{x} altogether $2 + 4 \cdot 2$ probabilities have to be estimated:

- $\hat{P}(\text{EnjoySport}=\text{yes}) = \frac{9}{14} = 0.64$
- $\hat{P}(\text{EnjoySport}=\text{no}) = \frac{5}{14} = 0.36$
- $\hat{P}(\text{Wind}=\text{strong} \mid \text{EnjoySport}=\text{yes}) = \frac{3}{9} = 0.33$
- ...

→ Ranking:

1. $\hat{P}(\text{EnjoySport}=\text{no}) \cdot \prod_{x_j \in \mathbf{x}} \hat{P}(B_{j=x_j} \mid \text{EnjoySport}=\text{no}) = 0.0206$
2. $\hat{P}(\text{EnjoySport}=\text{yes}) \cdot \prod_{x_j \in \mathbf{x}} \hat{P}(B_{j=x_j} \mid \text{EnjoySport}=\text{yes}) = 0.0053$

→ Normalization: (subject to conditions (c) and (d))

1. $\hat{P}(\text{EnjoySport}=\text{no} \mid \mathbf{x}) = \frac{0.0206}{0.0053+0.0206} = 0.795$
2. $\hat{P}(\text{EnjoySport}=\text{yes} \mid \mathbf{x}) = \frac{0.0053}{0.0053+0.0206} = 0.205$
